Introduction:

Recent studies have shown that FACS sorting and *in vitro* clonogenic assays are powerful tools for the isolation and quantitation of endogenous epithelial stem/progenitor cells (EpiSPC) [1].

approach together with *in situ*

in the trachea of CF and normal mice.

In a separate series of experiments we employed a polidocanol transient injury model to analyse the pattern of nasal airway epithelial cell proliferation and regeneration following *in situ* lentiviral (LacZ) reporter gene transduction of airway epithelial cells in normal mice.

Methods:

EpiSPC isolation and colony-forming assay:

Tracheal cell suspensions from normal, CF (UNC) and CF(FABP) mice were prepared by mincing and collagenase treatment.

CD24^{low} cells were isolated and co-cultured with mitomycin C treated fibroblasts together with supporting MLg cells to quantify the number of colonies (Epi-CFU)^[2]. The incidence of Epi-CFU in CF and normal tracheae was correlated with *in situ* measurement of epithelial cell proliferation by immunohistochemical detection of Ki-67 labeling.

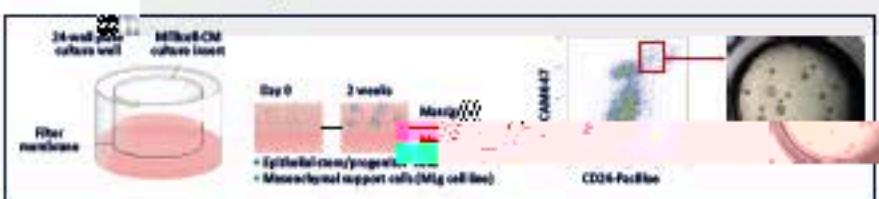

Figure 1: Schematic description of the lung EpiSPC assay system.

LPC/LV-LacZ reporter gene transduction:

Mice were pre-treated with 0.3% lysophosphatidylcholine in PBS followed by instillation of a HIV-1-VSV-G pseudo typed lentiviral vector carrying the LacZ gene^[3].

The Polidocanol transient injury model:

We employed a polidocanol detergent transient injury model to analyse the pattern of nasal airway epithelial cell proliferation following *in situ* lentiviral (LacZ) reporter gene transduction.

Following viral vector instillation, mice were randomly divided into three groups (n=11) with one group acting as a control. The second and third groups of mice received a single dose of polidocanol (doubling of dose at 4 weeks and 8 weeks) epithelium according to the methods described by Borthwick et al^[4].

Results:

Elevated incidence of Epi-CFU and of epithelial hyperproliferation in CF mouse trachea:

CD45⁺⁺CD31⁺⁺EpCAM⁺⁺CD24^{low} tracheal cell fraction of CF mice respectively compared to normal wildtype mice (Fig 1).

The incidence of proliferation of tracheal epithelial cells measured by *in situ* Ki-67 labeling was significantly higher in CF mice (Fig 2).

the incidence of proliferation of tracheal epithelial cells measured by *in situ*

Ki-67 labeling was significantly higher in CF mice (Fig 2).

the incidence of proliferation of tracheal epithelial cells measured by *in situ*

Ki-67 labeling was significantly higher in CF mice (Fig 2).

the incidence of proliferation of tracheal epithelial cells measured by *in situ*

Ki-67 labeling was significantly higher in CF mice (Fig 2).

the incidence of proliferation of tracheal epithelial cells measured by *in situ*
