**Introduction:**

Recently McQualter et al (PNAS 107:1414) prospectively isolated and characterized rare EpCAM<sup>pos</sup>α6-integrin<sup>pos</sup>β4-integrin<sup>pos</sup>CD24<sup>low</sup> multipotent adult lung epithelial and alveolar progenitor cells when co-cultured with lung stromal cells and cytokines. We have used this assay to compare the incidence and proliferative potential of EpiSPC in the proliferative activity of tracheal epithelium.

**Methods:**

The conducting airways from heterozygous (UNC) mice were used to quantify EpiSPC. Parallel studies analysed site-specific

**The lung epithelial colony-forming cell assay:**

CD45<sup>pos</sup>CD31<sup>neg</sup>EpCAM<sup>pos</sup>CD24<sup>low</sup> epithelial cells generate colonies (CFU) comprising cells of both airway and alveolar epithelial lineages when co-cultured in matrigel with Scα1<sup>pos</sup>EpCAM<sup>pos</sup> mesenchymal cells and mesenchyme-derived growth factors (Fig 1 & 2).

Figure 1: Schematic description of the lung EpiSPC assay system.

Figure 2: The clonal growth of CD45<sup>+</sup>CD31<sup>-</sup>EpCAM<sup>+</sup>CD24<sup>low</sup> EpiSPC reveals an obligatory requirement for mesenchymal support. The incidence and cell plate-forming potential is regulated by mesenchyme-derived stimulatory and inhibitory factors.

**Upper airway epithelial stem/progenitor cells in mouse models of cystic fibrosis:**

Using our assay we have shown a significant increase in airway progenitor cells in the trachea of cystic fibrosis mice. We detected a 5.2-fold and a 2.4-fold increase in the incidence of EpiSPC in the tracheal epithelia of CF (UNC) and CF (FABP) mice respectively, compared to normal heterozygous mice (Fig 4).

Figure 4: Histology and immunohistochemistry for Ki-67 in control and cystic fibrosis (CF) upper airways. (A) Histology of UNC trachea. (B) Histology of CF (UNC) trachea. (C) Immunohistochemistry for Ki-67 in UNC trachea. (D) Bar graph showing the percentage of Ki-67 positive cells in the tracheal epithelium for UNC, CF (UNC), and CF (FABP) mice.

**Upper airway epithelial stem/progenitor cell proliferation index:**

Sections containing excised tracheae were evaluated for stem/progenitor cell proliferation via immunohistochemistry for a nuclear proliferative antigen, Ki-67. A significant increase in Ki-67 positive cells was observed in the tracheal epithelium of CF (UNC) and CF (FABP) mice compared to heterozygous CF (UNC) mice. (Fig 4)

**Summary:**

These findings are consistent with the notion that expanded and dysregulated airway epithelial stem/progenitor cells may contribute to the progression of dysfunction in CF lungs and may represent a target for airway EpiSPC to sustain gene expression in a gene therapy setting.

**Acknowledgements:**

This work was supported by grants from the Australian National Health and Medical Research Council, Cure4CF Foundation, and the Farrow is supported by the MS McLeod Fellowship.
